A STABILITY STUDY OF NON-NEWTONIAN FLUID FLOWS

Corina CIPU¹, Carmen PRICINĂ², Victor ȚIGOIU³

The problem of the flow of a generalized Oldroyd –B fluid between two parallel plates is studied. We are interested if a von Karman type solutions are admissible for this fluid. We precise a frame of the problem from the point of stability view. We discuss some restrictions by certain inequality upon constitutive parameters. We determine the stability character of non–trivial base flows for Oldroyd–B fluid with constant material moduli.

Keywords: Oldroyd-B fluid, von Karman’s type solutions, stability character.

1. Introduction

By a stability study for an incompressible second grade fluid, from Clausius- Duhem inequality are obtained restrictions for the constitutive moduli of Cauchy stress tensor:

\[
\mu \geq 0, \alpha_1 + \alpha_2 = 0, \quad (1.1)
\]

and \( \alpha_1 \geq 0 \) if the free energy is to be minimum in equilibrium(see J.E. Dunn, R.L Fosdick [1]). In the paper of R. L. Fosdick and B. Straughan (see [2]), for instance, was investigated the instability in a fluid of third grade. Employing the Clausius- Duhem inequality and demanding that the free energy be a minimum in equilibrium, Fosdick and Rajagopal [3] have shown that the corresponding constitutive equation for an incompressible fluid of third grade is:

\[
\mu \geq 0, \beta \geq 0, \sqrt{24} \mu \beta \leq \alpha_1 + \alpha_2 \leq \sqrt{24} \mu \beta, \alpha_1 \geq 0. \quad (1.2)
\]

In [2], the authors assume that the inequalities (1.2) are strict inequalities. They show that the condition \( \alpha_1 < 0 \), which is compatible with the Clausius-Duhem inequality but not with the free energy, being a minimum in equilibrium and thus they lead to behavior which may not be physically acceptable.

2. The flow problem

The paper deals with the problem concerning the flow of a generalized Oldroyd–B fluid between two parallel plates. The Cauchy stress tensor is:

\[
T = -pI + T_E, \quad \frac{D T_E}{D t} + \frac{1}{\lambda} T_E = \mu A_1 + \alpha_2 A_1 + \alpha_1 \frac{D A_1}{D t}, \tag{2.1}
\]

where the convective derivative is expressed by (see Fetecau [4], [5]):

\[
\frac{D A}{D t} = \dot{A} + A L + L^T A. \tag{2.2}
\]

In the equation (2.1), \( T_E \) is the extra–stress tensor (effective stress – tensor), \(-pI\) denotes the indeterminate spherical stress, \( L \) is the velocity gradient, \( A_1 = L + L^T \) is the first Rivlin – Ericksen tensor, \( \lambda \) is the relaxation time, \( \mu \) is the dynamic viscosity, \( \alpha_1 \) and \( \alpha_2 \) are the constant constitutive coefficients. We have the constitutive restrictions (see Tigoi [6], [7]):

\[
\mu \geq 0, \alpha_1 + \alpha_2 = 0. \tag{2.3}
\]

The fluid flows between two parallel plates. The upper plate is supposed to be porous and the fluid passes through with constant vertical velocity, meaning:

\[
v(x,y)|_{y=d} = -v_0 \hat{j}, \tag{2.4}
\]

and the lower plate moves with the velocity:

\[
v(x,y)|_{y=0} = cx \hat{i}, \tag{2.5}
\]

where “d” is distance between the two plates, \( \hat{i} \) and \( \hat{j} \) are the unit vector in the horizontal and respective vertical directions and “c” is a given constant. We remark that the origin is preserved at rest (see Fig. 1).

![Fig. 1. Flow domain](image-001)
We shall suppose, like in [8], that the admissible velocity field is of von Karman’s type:

$$u = cxf' (\eta), v = -cdn (\eta), y = d\eta.$$  \hfill (2.6)

We study if a generalized Oldroyd -B fluid accept a von Karman’s solutions for the flow problem described above.

This flow field satisfies the constraint of incompressibility. Since the velocity field is independent of z, the stress field will also be independent of z. Therefore from the constitutive equation (1.1) we obtain the following system:

$$2c\mu f' - \alpha_1 (2c^2 f' f'' + \frac{c^2 \eta^2}{d^2} f'^2) = cxf' \frac{\partial T_{E11}}{\partial x} - cf \frac{\partial T_{E11}}{\partial \eta} + 2cf' T_{E11} + \frac{1}{\lambda} T_{E11}$$

$$c\mu \frac{x}{d} f'' + \alpha_1 (2c^2 f'' - f' f''' + \frac{c^2 \eta^2}{d^2} f''^2) = cxf' \frac{\partial T_{E12}}{\partial x} - cf \frac{\partial T_{E12}}{\partial \eta} + \frac{c}{d} f'' T_{E11} + \frac{1}{\lambda} T_{E12}$$

$$cx \frac{\partial T_{E13}}{\partial x} - cf \frac{\partial T_{E13}}{\partial \eta} + cf' T_{E13} + \frac{1}{\lambda} T_{E13} = 0$$

$$- 2c\mu f' + \alpha_1 (2c^2 f' f'' + \frac{c^2 \eta^2}{d^2} f' f''') = cxf' \frac{\partial T_{E22}}{\partial x} - cf \frac{\partial T_{E22}}{\partial \eta} +$$

$$+ \frac{2}{d} f'' T_{E22} - 2cf' T_{E22} + \frac{1}{\lambda} T_{E22}$$

$$cx \frac{\partial T_{E23}}{\partial x} - cf \frac{\partial T_{E23}}{\partial \eta} + \frac{c}{d} f'' T_{E13} - cf' T_{E23} + \frac{1}{\lambda} T_{E23} = 0$$

$$cx \frac{\partial T_{E33}}{\partial x} - cf \frac{\partial T_{E33}}{\partial \eta} + \frac{1}{\lambda} T_{E33} = 0. \hfill (2.7)$$

The equations of the motion are: \( \rho a = \rho b + \text{div} \mathbf{T} \). The acceleration is given by: \( \mathbf{a} = c^2 x (f'' - f''') \mathbf{i} + c^2 d f f' \mathbf{j} \). If we consider \( \mathbf{b} = 0 \), then the flow equations are:

$$\rho c^2 x (f'' - f''') = \frac{\partial T_{E12}}{\partial \eta} + \frac{d T_{E11}}{d x} - \frac{\partial p}{\partial x}, \hfill (2.8)$$

$$\rho c^2 d f = \frac{\partial T_{E22}}{\partial \eta} + \frac{\partial T_{E12}}{\partial x} \cdot \frac{\partial p}{\partial \eta} + \frac{\partial T_{E23}}{\partial \eta} + \frac{\partial T_{E33}}{\partial x} = 0.$$

We suppose that the effective stress is of the form:

$$T_{E}^{ij} = \sum_{n=0}^{\infty} \frac{1}{d^n} T_{E}^{n+ij} (\eta). \hfill (2.9)$$
Then we will be able to suppose that the pressure has the same type like
function $T_{ij}^E$ does:
\[ p(x, \eta) = p_0(\eta) + (x / d)p_1(\eta) + (x^2 / d^2)p_2(\eta). \]
(2.10)
If we use the relations (2.7)_3, (2.7)_5, (2.8)_3 we can determine the
expressions for the components $T_{E_1}^{13}, T_{E_{n}}^{23}$ and the equation for the function
$f(\eta)$. We remark that employing the relations: $T_1^{23} \equiv 0, T_2^{13} \equiv 0$, we arrive
at the following equation for $f$:
\[ \lambda \eta f'' + 6 \lambda \eta f' - 3 f' = 0. \]
(2.11)
Thus the problem is to solve the equation (2.11) under conditions obtained
from the described mechanical problem, which are:
\[ f(0) = 0, \quad f(l) = \frac{v_0}{cd}, \quad f'(0) = 1, \quad f'(l) = 0. \]
(2.12)
The problem is if the equation obtained for $f(\eta)$ has a solution if we
consider any two point problem of type (2.12). Using (2.12)_1 (2.12)_3 we found:
\[ c = 1/2\lambda. \]
(2.13)
Thus the equation (2.11) becomes:
\[ f'' f^2 + 6 f' f^2 - 6 f' = 0. \]
(2.14)
For the study of the above problem, we first develop the function $f$ in
power series, in order to determine the coefficient of second order in $\eta$:
\[ f(\eta) = a_0 + a_1 \eta + a_2 \eta^2 + a_3 \eta^3 + ... a_n \eta^n + ... \]
(2.15)
From (2.12)_1 (2.12)_3 we calculate that:
\[ a_0 = 0, a_1 = 1, a_2 = 0.5 = \frac{v_0}{cd}. \]
(2.16)
For the second approximation (of $f$) in $\eta$ we make a change of the
function introducing a new function $h(1-\eta)$:
\[ f(\eta) = \eta + a_2 \eta^2 - h(1-\eta) \eta^2, \]
(2.17)
getting for $h(t)$, $t = 1-\eta$, a differential Cauchy problem:
\[ (1-t)^5((2-t)h - 3)hh' = (1-2h + 4(1-t)h')(1-t)^3 h((1-t)h - 3 + t) + 
+ 6(2-t - 2(1-t)h + (1-t)^2 h')^2 - 6(2-t - 2(1-t)h + (1-t)^2 h')(1-t)h(1-t)h - 3 + t) + 
h(0) = 1, h'(0) = 0. \]
(2.18)
By a numerical calculus we determine the function $h$ only for
$\eta \in [0, 0.62]$, fit the data of function $h$, and obtain a seventh degree polynom (see
Fig.2). The value $\eta = 0.62$ express the first point for which $h(\eta) = 0$. For
$\eta \in [0.62, 1]$ we shall use the fitted polynom, $h$ being a continuous function.
Fig. 2 Computed function $h$ and fitted polynomial

The approximation of $h$ over the interval $[0, 0.62]$ is:

$$h(t) \approx 840t^7 - 1200t^6 + 540t^5 - 48t^4 - 24t^3 + 4.4t^2 - 0.24t + 1,$$  
(2.19)

and the $f$ approximation by polynomial over the same interval is:

$$f \approx \eta + 0.5\eta^2 - \eta^2 [840(1-\eta)^7 - 1200(1-\eta)^6 + 540(1-\eta)^5 - 48(1-\eta)^4 - 24(1-\eta)^3 + 4.4(1-\eta)^2 - 0.24(1-\eta) + 1].$$  
(2.20)

3. Stability of the solution by numerical analysis

For the fluid studied, now we consider a small perturbation of the base flow. The perturbed flow is given by the following expressions:

$$\tilde{u} = cx(f'(\eta) + \phi'(\eta)) = u + \tilde{u}, \quad \tilde{v} = -cd(f(\eta) + \phi(\eta)) = v + \tilde{v}. \quad (3.1)$$

Since $\tilde{u}, \tilde{v}$ are given by the same equations of motion like $u$ and $v$ does, the small perturbation $\tilde{u}, \tilde{v}$, must satisfies:
\[ g''(f^2 + 2\varepsilon g) + 6g'(2f' - 1 + \varepsilon g') + g f''(2f + \varepsilon g) = 0, g(0) = \varepsilon^2, g'(0) = 0 \]

(3.2)

neglecting \( O(\varepsilon^2 g^2) \) in respect with \( O(f) \).

6. Conclusions

Our study conclude that existence of von Karman type solution for the Oldroyd–B fluid implies a certain constants for obtaining dimensionless values of the velocity: \( c = \frac{1}{2\lambda} \), and \( v_0 = 2cd \). Also, we observe that small perturbations of the base flow are numerically stable \( (O(g) \approx O(\varepsilon^2) \) as were imposed initially in \( \eta = 0 \), see Fig. 4).

BIBLIOGRAPHY
